Understand how a river forms and how it changes downstream. Studying the long profile of a river is useful because the students can see how the UK landscapes can vary and identify these when they are exploring the UK themselves. What causes a river to flood – this provides students with an understanding of how their actions can lead to a flood. It also helps them to identify where flood risk areas are so that they can protect themselves in the future.

	Processes in a river:	Helps students to understand why
	ETD – Erosion, Transportation and Deposition	the river systems in the UK look the
	– EROSION	way they do.
	1. Vertical erosion involves the deepening of the river bed. This is mostly by hydraulic	
	action. It is most common in the upper course of the river.	Linking the knowledge they gain
	2. Lateral erosion erodes the banks of the river. This is more common in the middle	from the topic, to a real-life
	and lower courses of a river.	example of places along the River
	3. 4 types of erosion - Abrasion (corrasion), attrition, hydraulic action and solution or	Tees. This helps the students to
	(corrosion).	better understand areas in the UK,
	4. Hydraulic action is when the force of fast-flowing water hits the bed and banks and	in order to broaden their
	forces water and air into cracks in the bedrock. The repeated changes in air	knowledge of areas outside of
	pressure cause the river bed to weaken.	Mansfield.
	5. Abrasion, also known as corrasion, is when boulders and stones wear away the	
	river banks and bed. Angular rocks that have entered the channel (usually in the	DME – allowing the students to gain
	upper course) recently are useful tools of abrasion because they are more angular	experience in deciding the best
	(sharpe). Abrasion is responsible for both lateral and vertical erosion of the river	solution for managing flood risk in
	channel	an area. This is useful for their
	6. Attrition is when sediment particles knock against the bed or each other and break,	future career development.
	becoming more rounded and smaller as you move down the river.	
	7. Solution (or corrosion) is when acidic water dissolves rocks such as chalk or	
	limestone.	
	TRANSPORTATION	
	1. 4 types - Solution, suspension, saltation and traction.	
	Large boulders and rocks are rolled along the river bed – traction.	
	3. Small pebbles and stones are bounced along the river bed - saltation.	
Cross profile –	4. Fine, light material is carried along in the water – suspension.	
remember types of	5. Minerals are dissolved in the water and carried along in solution - solution.	
erosion for		
understanding how	DEPOSITION	
rivers are eroded	 Deposition is the processes by which a river drops its load. 	
laterally.	2. Deposition occurs whenever a river loses energy and velocity falls.	
	3. Deposition occurs:	
	 a river enters a shallow area (this could be when it floods and comes into contact 	
	with the flood plain)	

	at the base of a waterfall	
	on the inside bend of a meander	
	towards its mouth where it meets another body of water.	
	THE CROSS PROFILES OF A RIVER	
	1. River cross profiles show you a cross-section, taken sideways, of a river's channel	
	and/or valley at certain points in the river's course.	
	2. A channel cross-profile is a cross section of only the river channel.	
	valley.	
	4. In the upper course the channel is very narrow and very shallow. By the middle	
	course the channel becomes wider and deeper usually over 1 m. By the lower	
	course the channel becomes wider still and the channel is much deeper.	
	5. In the upper course, the river erodes its bed by hydraulic action and abrasion. As	
	the river flows downstream it is joined by tributaries, increasing the volume of	
	water, velocity and therefore its erosive power. This enables it to cut a deeper	
	channel as it flows downstream.	
	6. Downstream, the channel becomes wider as the gradient becomes more gentle	
	leading to less vertical erosion. By the middle course of the river lateral erosion	
	becomes the dominant type of erosion. The channel becomes wide because of	
	lateral erosion.	
	6. In the upper course, the valley cross-profile is narrow and steep-sided. The river	
	takes up most of the valley floor. In the middle course, the valley becomes wider	
	due to lateral erosion. By the lower course, the valley is almost flat, consisting of a	
	wide flood plain.	
	7. A steep, V-shaped cross-profile is typical in the upper course. This is because of	
	vertical erosion by the river combined with weathering and mass movement of the	
	valley slopes.	
Must know what the	8. In the middle course, the river is flowing through lower lying land. The gradient is	
upper course is to	gentler, so the river begins to meander (bend). As it does this the dominant type of	
understand its features.	erosion becomes lateral, eroding the valley sides. The makes the valley	
	broader. Also, the rate of weathering increases on the softer rocks of the valley	
	sides.	
Must understand the		
processes of erosion to		

understand how upper	9. In the lower course, the river is passing through the low-lying country. Flooding	
course features are	results in deposition building up the flood plain and this, along with migrating	
created.	meanders builds up and widens the valley further.	
	Upper course features (landforms):	
	1. Interlocking spurs are fingers of land that jut out into the river valley that streams	
	and rivers are forced to flow around in the upper course.	
	2. Steep gradient, convex slopes, separated by a narrow valley floor which is mainly	
	taken up by the river channel, sometimes covered in Woodland and may have	
	scree slopes.	
	WATERFALLS AND GORGES	
	1. Waterfalls and gorges are typically found in the upper course of the river.	
	2. A waterfall is a step in the long profile of the valley. It is where water falls down the	
	vertical drop in the channel usually from a considerable height.	
	Formation of a waterfall:	
	1. Waterfalls often occur when a layer of hard, resistant rock lies over a layer of softer	
	rock	
	2. The river's bedload swirls around at the foot of the waterfall, gradually eroding the	
	riverbed to form a plunge pool – through hydraulic action, abrasion and attrition	
	3. The less resistant rock is eroded more quickly, undercutting the harder rock to form	
	an overhang. This overhang eventually collapses under its own weight	
	4. Over many years this process is repeated many times and the waterfall retreats	
	upstream leaving behind a steep-sided valley called a gorge.	
	Formation of a gorge:	
	1. As a waterfall it leaves behind the steep sided valley which is called a gorge. Every	
	time the overhanging rock breaks off the gorge retreats and grows longer.	
Must know the		
processes of erosion and	A gorge is a narrow, steep sided valley, with bare, rocky walls	
deposition to know how	Characteristics of gorge include:	
oxbow lakes are formed.	1. very narrow valley	
	2. very steep, high valley sides is	
	3. located immediately downstream of a waterfall	
	4. river channel takes up most, if not all, of the valley floor	
	5. boulders litter the riverbed	
	6. turbulent, fast flowing whitewater	<u> </u>

irosion www.channel

deposits

Oxbow /a

Must understand the process of deposition to know how levees are formed.

3. Due to a solution of the outside of a bend and deposition on the inside, the shape of a meander will change over a period of time. Erosion narrows the neck of the land within the meander and as the process continues, the meanders move closer together. When there is a very high discharge (usually during a flood), the river cuts across the neck, taking a new, straighter and shorter route. Deposition will occur to cut off the original meander, leaving a horseshoe-shaped oxbow lake.

Levees are naturally raised riverbanks found along the sides of the river channel that has experienced flooding.

The main characteristics of levees are:

- 1. Raised river banks
- 2. Consist of gravel, stones and small sediment

veand

- 3. Steep on the channel side, gentle sloping on the land side
- 4. Relatively flat top covered in grass

	Formation of levees:	
	When a river floods, friction with the floodplain leads to a rapid decrease in the velocity of the river and therefore its capacity to transport material. Larger material is deposited closest to the riverbank, because the energy of the river slows and cannot hold on to the larger material, so they are deposited first. This often leads to large, raised mounds being formed. Smaller material is deposited further away and leads to the formation of gently sloping sides of the levees.	
	Floodplains:	
	A flood plain is a large area of flat land either side of the river that experiences or has experienced flooding.	
Must understand the process of erosion and deposition to know how a floodplain is formed.	 Characteristics of a flood plain include: 1. A large area of flat land either side of a river 2. Layers of alluvium cover the flood plain 3. A river bluff along the edge of a flood plain 4. Meander scars 5. Levees 6. Rich, fertile soil 7. Reeds and marsh plants Formation of floodplains:	
Must understand the processes of ETD, formation of upper, middle and lower course landforms, to apply this	Floodplains form due to erosion and deposition. Erosion removes any interlocking spurs, creating a wide, flat area on either side of the river. During a flood, material being carried by the river is deposited (as the river loses its speed and energy to transport material). Over time, the height of the floodplain increases as material is deposited on either side of the river. The floodplain is often a wide, flat area caused by meanders shifting along the valley. It's made up of alluvium (deposited silt from a river flood).	
	Estuary formation:	

to the case study of the	An estuary is the tidal part of a river – where the channel widens as it reaches the sea.
River Tees	Characteristics:
	Is the point where freshwater (river) meets with salt water (sea).
	Can be very wide
	May have a tidal bore – this is where huge waves funnel up the river as the tide comes in.
	Will have mudflats – visible at low tide (some mudflats may have salt marshes on).
	Estuary formation & development:
	1. As sea-levels rise (e.g. After ice age), low lying valley sides either side of rivers were
	flooded creating estuaries (e.g. The Severn Estuary).
	2. Where fresh and salt water meet and during a rising tide the river's velocity falls
	and sediment is deposited. This forms extensive mudflats in sheltered areas
	(exposed at low tide)
	3. Over time these may develop into saltmarshes.
	EXAMPLE OF A RIVER VALEY IN THE UK
	The River Tees
	Landforms of erosion will be identified and include waterfalls, interlocking spurs, gorges
	and meanders.
	Landforms of deposition will be identified and include meanders, levees and floodplains.
	Upper course:
	The source of the River Tees is high up in the Pennines (893m ASL) close to Cross Fell at
	Tees Head.
	High Force Waterfall – located in the upper course of the River Tees close to Forest-in-
	Teesdale. Has a 20m drop into a turbulent plunge pool. An impressive gorge runs approx
	/UUM. Consists of resistant whinstone (dolerite) rock overlying weaker carboniferous
	iviladie course:

The Ri with ir	ver Tees becomes less steep as it enters its middle course and meanders develop creased lateral erosion. The River Tees meanders it way through a lower gradient	
past B	arnard Castle.	
Lower	course:	
There an ox-	is a sweeping meander at Sockburn (near Darlington) – may eventually develop into bow lake as the neck of the meander becomes narrower.	
Floodi examp	ng has caused the development of raised banks (levees) along the lower course – for Ie near Neasham.	
The Ri at Mic	ver Tees flows roughly east from its source for around 128km to reach the North Sea dlesbrough at its mouth.	
The Te	es Estuary is wide with mudflats and sandbanks, formed by sea-level rise at the end last ice-age. There are parts of the estuary important for wildlife and have become	
have c	eveloped along the estuary.	
PHYSI	CAL CASUSES OF FLOODING	
1.	The drainage basin hydrological cycle shows how precipitation, falling on	
	catchment areas, reaches a river. It also shows how water leaves the catchment area.	
2.	Precipitation is any form of moisture reaching the ground.	
3.	Interception is when precipitation is prevented from reaching the ground. This could be by vegetation or buildings.	
4.	Surface run-off is when water flows over the surface of the ground.	
5.	Evaporation is when water is lost from the ground as it turns from liquid to vapor due to an increase in temperature or pressure.	
6.	Transpiration is the loss of water from vegetation through pores.	
7.	Natural ways flood risk can be increased include:	
- heav	y rainfall caused by depressions causing heavy, continuous rain which saturates the	
soil. T	ne land can no longer absorb water as it is saturated increasing surface run-off,	

	-sudden downpours occurring following a very dry period can lead to flooding because the	
	surface is baked hard. Surface run-off occurs as water cannot infiltrate leading to higher	
	river discharge and flooding.	
	-sudden snow melt releases stored water that flows over the land as surface run-off	
	-the loss of vegetation cover through drought or disease can lead to flooding as less	
	interception occurs so more precipitation reaches the surface leading to increased surface	
	run-off.	
	8. Geology can increase the risk of flooding when:	
	-The upland bedrock is impermeable, such as slate, which means there is more surface	
	run-off	
	-Soil in low lying areas is made up of clay. Because it is so compact it is difficult for	
	infiltration to occur.	
	-Areas of permeable rock, such as limestone, become inundated with water leading to	
	increased surface run-off	
	-Relief can increase flood risk because:	
	-Steep sided slopes mean that it is hard for infiltration to occur which leads to greater	
	surface run-off	
	-Low lying flood plains are at risk of flooding because they do not have enough gradient to	
	move the water on quick enough. This risk increases when the soils have a high clay	
	content.	
Hydrological cycle links	-Upland areas are more likely to experience rain due to relief rainfall. This increases the	
to the key words - runoff	likelihood of high levels of precipitation and therefore surface run-off.	
and infiltration when		
understanding flood risk.	HUMAN CAUSES OF FLOODING	
	Three ways humans can increase the risk of flooding in urban areas are:	
	-Building new infrastructure	
	-Building new houses	
	-Disappearing gardens	
	Three ways humans can increase the risk of flooding in rural areas are:	
	-Deforestation	
	-Intensive farming, leaving fields bare in the winter	
	-Over grazing	

Understand the keys word precipitation for hydrographs.	Building a new housing estate on the floodplain increases the risk of flooding because the surface becomes impermeable due to the construction of houses, tarmac roads and concrete pavements. Surface run-off increases leading to a rapid increase in a river's discharge.	
Must know what the word discahrge is for hydrographs. Must understand how different types of land use can influence a hydrographs – such as the urbanisation, causing more surface runoff leading to a shorter lag time.	 A hydrograph is a way of showing how a river's discharge changes in response to a precipitation event. Precipitation and discharge Time The highest amount of rainfall per time units (the highest bar). The highest discharge following a rainfall event. The time between the peak rainfall and the peak discharge. How quickly the discharge increases after a storm event. Shows the reduce in discharge over time after the peak. The normal discharge of a river when its level is being sustained by groundwater flow. The maximum discharge level before flooding will occur. A flashy or storm hydrograph will have a steep rising limb and a short lag time. RIVER MANAGEMENT: HARD ENGINEERING Hard engineering involves the use of heavy machinery to build artificial structures which work against nature to reduce a flood risk. Examples of hard engineering include: Dams and reservoirs Channel straightening Embankments Flood-relief channels A social cost of constructing dams and reservoirs is the displacement of people due to flooding 	

One economic benefit of constructing dams and reservoirs is that it boosts tourism. For	
example, the local economy of Kielder has been boosted by £6 million thanks to the	
construction of Kielder Dam.	
Benefits of embankments:	
Social:	
Safer from flooding due to the increased carrying capacity of the river so the risk of	
flooding to nearby settlements is reduced.	
Embankments are often used for walking routes which makes the embankment a more	
attractive walkway for local people.	
Economic:	
Cheap compared to other methods of hard engineering	
Environmental:	
Habitats are provided for riverbank animals such as otters, voles and kingfishers	
RIVER MANAGEMENT: SOFT ENGINEERING	
Soft engineering involves working with nature and adapting to a river and learning to live	
with it.	
Flood warnings, flood plain zoning, planting trees and river restoration.	
Low cost solution, reduces additional impermeable surface coverage of the floodplain,	
protects and conserves water meadows for wildlife and recreation and reduces insurance	
costs when property has been flooded	
Restricts economic development as certain land uses are prohibited, if land cannot be used	
for building the current housing shortage will continue, through building elsewhere	
habitats may be lost, and it is very difficult to implement retrospectively where urban	
development has already taken place on the floodplain.	
Benefits wildlife by creating habitats, natural method of intercepting precipitation and	
slowing water transfer in a river basin, absorbs and stores carbon reduce the amount of	
carbon dioxide in the atmosphere and it is relatively inexpensive.	

	Can reduce habitat diversity when hillsides are covered in trees, can lead to acidity in soil	
Recap – understanding	and the loss of farm land.	
why there is a need to		
manage an area from	EXAMPLE OF A FLOOD MANAGEMENT SCHEME IN THE UK	
flooding.		
	Banbury UK	
	Banbury is a historic market town on the River Cherwell in Oxfordshire, England.	
	Banbury is located in the north of Oxfordshire. In the Cotswold Hills about 50km north of	
	Oxford. Population about 45,000.	
	W/by is there a problem?	
	Ranhury is located on the flood plain of the River Cherwell – this is a tributary of the River	
	Thames. The geography & geology of the valley that the River Cherwell runs through	
	makes Banbury particularly susceptible to flooding	
	There has been a history of devastating floods in Banbury.	
	1998 and 2007 both experienced devastating floods.	
	1998 Flood effects:	
	closure of town's railway station	
	£12.5 million damage	
	150 homes and	
	businesses affected.	
	Flood management scheme:	
	The Environment Agency are responsible for managing flood risk.	
	The construction of a new defence scheme started in 2011 and was completed in 2012,	
	with five major strategies to try and reduce the chances of flooding in the future.	
	Strategy 1- Road Raising	
	860 metres of the A361 was raised in the flood storage area and culverts (small tunnels) to	
	improve drainage beneath road to reduce flooding.	
	Strategy 2. Pumping Station built	
	Pumping station built at Moorfield Brook to transfer excess rainwater into the river	
	downstream of the town.	

Strate New 2 and sp	gy 3 – Earth Embankments and Floodwalls 2m high, 400m long earth embankment to protect the industrial estate from flooding pecifically, a flood wall built around the site of prodrive (a motorsport business).	
Strate New h	gy 4 – A Biodiversity Action Plan (BAP) nabitats, including ponds, trees and hedgerows provide greater interception and	
areas	to absorb and store excess water to reduce flood risk.	
Strate	gy 5 – Flood Storage Area	
A new to the pools. the riv an op reserv	v flood storage area has been created by building a 2.9km earth embankment parallel M40 – it can hold 3 million cubic metres of water, 1200 Olympic size swimming On the natural floodplain, collecting rainwater that otherwise would have caused ver to swell and flood. Within the flood embankment there is a control structure with ening which controls the rate of flow. Excess water builds up behind, filling the voir and protecting Banbury beyond.	
Positiv	ves and negatives of the scheme:	
•	The raised A361 into Banbury will remain open in flood, reducing disruption for people.	
•	Cost of scheme – about £18.5 million	
•	Quality of life improved for people with new green areas / footpaths.	
•	Around 100,000 tonnes of earth needed for embankment – created a small reservoir	
•	New Biodiversity Action Plan created new habitats	
•	By protecting 441 houses / 73 businesses the benefits are estimated to be over £100 million	
•	Part of the floodplain will be allowed to deliberately flood if river levels are high	
•	Reduced levels of anxiety / depression as reduced flood risk.
